## Lab Manual

Module- 02

**Course Title** : Sessional based on CSE 2201

**Course No.** : CSE 2202

**Name:** Complexity analysis of searching algorithm (Linear search and Binary search)

**Algorithms:**

- Linear Search
- Binary Search

### Linear Search

**Iterative**

Suppose an array A with elements indexed 1 to n is to be searched for a value x. The following pseudo code performs a forward search, returning n + 1 if the value is not found:

Linear\_Search(A,x)

Set  $i$  to 1.

Repeat this loop:

    If  $i > n$ , then exit the loop.

    If  $A[i] = x$ , then exit the loop.

    Set  $i$  to  $i + 1$ .

Return  $i$ .

**Recursive**

Linear search can also be described as a recursive algorithm:

LinearSearch(value, list)

    if the list is empty, return  $\Lambda$ ;

    else

        if the first item of the list has the desired value, return its location;

        else return LinearSearch(value, remainder of the list)

**Task:**

1. Find out the complexity of these two algorithms for linear search mathematically.
2. Code these algorithm in any language(i.e. C/C++/Java)
3. Find the running time for a set of list (let size 1000, 5000,10000, 15000 etc) search a value x.
4. Write down a report on it.

### Binary Search

**Iterative**

```
BinarySearch(A[0..N-1], value) { low =  
    0  
    high = N - 1  
    while (low <= high) { mid =  
        (low + high) / 2 if (A[mid] >  
        value)  
            high = mid - 1  
        else if (A[mid] < value) low =  
            mid + 1  
        else  
            return mid // found  
    }  
    return -1 // not found  
}
```

## Recursive

The most straightforward implementation is recursive, which recursively searches the sub range dictated by the comparison:

```
BinarySearch(A[0..N-1], value, low, high) { if
    (high < low)
        return -1 // not found
    mid = (low + high) / 2
    if (A[mid] > value)
        return BinarySearch(A, value, low, mid-1)
    else if (A[mid] < value)
        return BinarySearch(A, value, mid+1, high)
    else
        return mid // found
}
```

### Task:

1. Find out the complexity of these two algorithms for linear search mathematically.
2. Code these algorithm in any language(i.e. C/C++/Java)
3. Find the running time for a set of list (let size 1000, 5000,10000, 15000 etc) search a value x.
4. Write down a report on it.

Now Compare between linear search and binary search and write down a report on it.
